- 3 Discuss Inscition Soit and Selection Soit With examples.
- in Insertion Sort:

Insertion Leit works by inserting the set of halves in the existing sorted file. It constructs the sorted array by inserting a single element at a time. This process continues until whole array is sorted in same order. The primary concept behind insertion sort is to insert. The primary concept behind insertion sort is to insert. each item into its appreciate place in the final list. The insertion sort method saves an effective ammount of memory.

Morking of incertion cost.

- → It was two sets of aways where one stores the sorted data and other on unsorted data.
- → the sorting algorithm works untill there are elements in the unsorted set.
- → lets assume there are 'n' numbers elements 9n the assay. Initially, the element with index O(LB=0) exists in the sorted set glemaining elements are in the unsorted partition of the list.
- -The first element of the unsorted portion has array index 1 (if LB = 0)
- -> After each iteration, it chooses the first element of the insorted position and inserts it into the proper place in the sorted set.
- -Advantages of Insertion soit!

With a distribution

-> Fasily implemented and very efficient when wed with small sets of data.

- sort is less (i.e. (0(1))).
  - the list can be sorted at the new elements are.
- > It is faster than other sorting algorithms.

# (omplexity of Insertion sort:

The best ease complexity of inscition sort is o(n)

-times, i.e When the array is previously sorted. In

-the same vary, when the array is sorted in the.

teverse order, the first element in the unsorted array is to be composed with each element in the sorted set. So, in the worst case, sunning time of insertion sort is quadratic, i.e. (o(n2)). In average case also it has to make the minimum (k-1)/2 comparisions.

-tener, the average case also has quadratic running time

### Example :-

arren= 46 22 11 20 9

. Il Find the minimum element in arr [0.... u] and place at beginning.

9 46 22 11 80
Il Find the minfmum element in arr [8 1,.... 4] and.
Place at begining of arr [1..... 4]

911 46 22 20.

Il Find the minimum element in all [2.... 4] and.
Place at begining of all [2... 4]

ી 11 લઇ પર 22.

I Find The minimum element in the array a [3...4] and insert at the begining of the array [3...4]

.. Sorted array

9 11 20 22 46.

#### <u>Selection</u> Sort:

The Selection sort perform sorting by searching for the minimum value number and placing it into the tirst or last position according to the order (ascerding or decending). The process of Searching the minimum key and placing if in the proper position is continued until time all the elements are placed at light position.

## lalorking of the selection sort:

- -Suppose an array Arr & with n elements in the memory.
- → In the first pall, the Smallest key is searched along with hits position then the Arr [Pos] is supposed and swapped with Arr[D]. Therefore Arr [D] is sorted.
- In the second pass, again the position of the smallest value is determined in the subarray of (n-1) elements inter change the Arripos with Arrill
- to soit the n number of elements.
- -Advantages of Selection sorti-
- Is Performs well on a small list.

### Scarnica with Can

> Purther more, because it is no in place sorting.

algorithm, no additional temporary storage is

stepurated beyond what is needed to hold the original

# Complexity of selfdion cost:

-As the Morking of selection soil does not depend on the original order of the elements. In the array, 30 there is not much difference between best case and worst case complexity of selection soil. The .

Selection soil The selection soil selects the minimum value element, in the selection process the minimum number of elements are scanned, therefore not comparisions are made in the first pass. Then, the elements care into changed. Similarly in the scient Raw also to find the Second Smalled element we slequite scanning of test notelements and the process is. Continued till the whole array sorted. Thus sunning. Time complexity of selection soil is  $O(n^2) = 0$ .

(n-1)+ (n-2)+ --- - - 1)+1= n(n-1)/2 = 0(n))

#### Example:-

13 12 14 6 7.

let us loop for i= 1 (second element of the array ) to a (last element of the array).

7= 1. Since 12 is smaller than 13, move 13 and insect.

12 before 13.
do same for 1=2, 1=3,1=4.

. Soiled awray.

6 7 12 13 14
